- Portions of the screen that exhibit certain behavior are called '*Components*' in Angular

- One can define as many logical components as he/she wants, there are no rules

- Example components in a ecommerce application would be cart, navigation, products details, product list etc.

- A component in Angular version 6 using CLI is created by running the command
  `ng generate component <component name>`

- A component folder created will typically include an HTML file (*Template*), a css file, a typescript file for the component business logic, and a user can create another typescript file for a *Service* in that folder

- Template displays the data passed on by corresponding component file

- A component file receives or sends data to a service, and processes the data received from service before forwarding it to a template. The process is called *data binding.*

- A service handles the logic that is not related to the UI such as backend interaction

| HTML template (e.g. cart.html) | ↔ | A component file (e.g. cart.component.ts) | ↔ | A service file (e.g. cart.service.ts) |

CSS file (e.g. cart.css)

Other important concepts in Angular
